13 March 1995

Abstract

Upper Ocean Processes Group meteorological data is transmitted from surface buoys via Argos satellite and processed in an automatic mode on a UNIX workstation. Data is extracted from input files based on instrument type and experiment, processed as appropriate, and plotted, without user intervention. While the processing system normally runs automatically, it is designed so that modules can also be run directly from a terminal when necessary. The Argos processing system allows us to monitor the meteorological data being collected in the field, and provides early information about problems with sensors, instruments, or buoys, when they occur. The automatic process allows more information to be viewed with less effort, and increases the usefulness of the Argos data.

1 UNIX Implementation and Overview

Data transmitted from surface buoys via Argos satellite for the Upper Ocean Processes (UOP) Group experiments are processed in an automatic mode on a Sun workstation, Griffon, using a series of shell scripts and C programs initiated by the UNIX cron utility. Files of data from all of the UOP's active Argos transmitters are sent daily from Service Argos' computers in Landover, Maryland, using ftp. The UNIX cron utility runs a script every hour which checks for incoming data. When a new data file is found, processing scripts are activated.

Each platform transmitter terminal, or PTT, in the field includes its own identification number in the messages it sends to Service Argos. This number allows Service Argos to route each message to the correct destination, grouping the messages it receives for retransmission to the PTT owner. Each PTT identification number is associated with an experiment number, which is used for routing and accounting purposes, and so data for each experiment is bundled into a separate file. Currently, we receive data from our Arabian Sea buoy in a file called argos.dat, and data from our GLOBEC buoy in file argos2.dat.

Incoming data is processed by a suite of C programs and shell scripts. While these programs and scripts are normally run automatically by the UNIX scheduler, cron, they are designed so they can also be run directly from a terminal in cases where Argos transmissions are interrupted, an instrument must be reprocessed, or non-standard plots are desired.

The primary goal of the Argos processing system is to monitor the meteorological data being collected in the field, as soon as it becomes available. The system also provides early information about problems with sensors, instruments, or buoys, when they occur. By automating the entire process, we allow more information to be viewed with less effort, and increase the usefulness of the Argos data.

1.1 Cron

The UNIX cron utility is currently run by user nan on Griffon. Cron executes commands at specific times. The commands are entered into a table, called the cron table, by program crontab. The cron table entry on Griffon can be edited by its owner by typing crontab -e. New cron table entries can be started using crontab -e, or checked by typing crontab -l. The cron table entry for the Arabian Sea and GLOBEC Argos processing is:

```
1 * * * * /gdata/argos/argos.sh
1 8 * * 1-5 /puli/data/arab/argos/dopl.sh
1 8 * * 1-5 /puli/data/globec/argos/dopl.sh
```

The first entry runs the script argos.sh at one minute past every hour, every day. The second and third commands generate plots at 8 a.m. on weekdays only, using plotting scripts for two experiments in their processing directories.

The crontab entries are basically names of shell script programs. To change the processing system, the scripts themselves can be edited, without having to alter the crontab entry. As experiments start and end, the appropriate commands can be added to or deleted from the main processing scripts.

The directory /gdata/argos on Griffon contains all the shared processing software and has subdirectories for each active experiment. These experiment subdirectories contain archives of Argos data and information about the instrumentation. The processed data normally resides, along with experiment-specific scripts, on another workstation, on a disk that is mounted on Griffon using the Network File System (NFS).

If data must be retransmitted from Service Argos for any reason, argos.sh will automatically process any new data every hour. As long as Service Argos does not send more than one file within that time period, cron will cause argos.sh to copy and process all incoming data files with the names

specified in the script. To process an incoming file immediately, the script `argos.sh` can be invoked from the keyboard.

2 Main Processing Script

The main processing is initiated by the shell script `argos.sh`, in Griffon's directory `/gdata/argos`. Incoming Argos data is written to that directory in files named `argos.dat` and `argos2.dat`, which represent two different Argos accounts. This script handles each input file separately, first processing all data in `argos.dat.n`, then `argos2.dat.n`.

For each experiment, the script first checks for the existence of the appropriate incoming data file. If the file exists, it is moved to a file named `argos(2).dat.n`, where `n` is a monotonically increasing number. Note that if the file `argos.dat.1` does not exist, that filename is used for the new file. If it does exist, the directory is checked by the shell script `findlast.sh` to determine the next sequence number for the output filename, which is numerically one greater than the highest existing number. Therefore, removing the file `argos.dat.1` will cause erratic numbering, since the next file processed will be called `argos.dat.1`, but incoming data files will never be overwritten by the automated processing system.

Once the file archiving is done, the script processes data from the Vector-Averaging Wind Recorder (VAWR), then data from the Improved Meteorological (IMET) System, if it is being transmitted. If IMET data is not transmitted, there is normally a tensiometer reporting, and its data is processed after the VAWR data. Position data, generated by the Argos system, is processed last. Processing each of these data sets requires a separate pass through the incoming file, looking for the appropriate Argos transmitter ids. Each of these tasks is handled by an independent shell script, which can be run manually if needed.

See Appendix I for text of the shell scripts `argos.sh` and `findlast.sh`.

3 Processing VAWR Data

The script `argos.sh` processes VAWR data using another shell script, `gargle.sh`, which in turn runs a C program to extract and scale the incoming Argos data. Shell script `/gdata/argos/gargle.sh` starts one of the gargle processing programs, which extract VAWR data from a specified Argos input file based on information in a calibration file.

The VAWR data files produced by this system contain the variables yearday, wind east, wind north, wind speed, wind direction, short wave radiation, relative humidity, barometric pressure, sea temperature, air temperature, long wave thermopile voltage, body temperature, dome temperature, and long wave radiation. Air and sea temperatures are recorded in degrees centigrade, while body and dome are Kelvin temperatures. Wind vectors are recorded in meters per second, radiation values in watts per square meter, and thermopile voltage in microvolts. Relative humidity is reported as a percentage, and barometric pressure is reported in millibars. A sample output file is contained in Appendix II.

This system uniformly uses the convention that yearday 1 begins at midnight on January 1. This is consistent with the UNIX date utility, which is used to check for invalid dates and to set date limits for plots.

Occasionally VAWR data will need to be reprocessed. This will usually occur when corrections need to be made to a table file. If a VAWR's interval counter resets, the date calculated by the software system will be incorrect, and the data will need to be reprocessed after a table file change has been made. To reprocess VAWR data in case of errors or resets, remove any unwanted or incorrect data from the file `/gdata/argos/exper/vawrnnnn.arch`, which is appended by the processing system. Then `cd` to `/gdata/argos` and type

```
gargle.sh garglenew argos.dat.nn exper vawrnnnn >>  
/gdata/argos/vawrnnnn.log 2>&1
```

where nn is the number of the argos.dat file to be reprocessed, exper is the experiment name and nnnn is the 4-digit VAWR number. The experiment name must correspond to two data directories, one in /puli/data and one in /gdata/argos. The first, /puli/data/exper, must have a subdirectory named argos, and the second, /gdata/argos/exper, must contain a table file for the VAWR to be processed.

Note that the working data file in the processing subdirectory on Puli is overwritten daily by the automated processing system, so any changes made there will be lost. To permanently alter the working data file, the archive version of the file, in the /gdata/argos directory, must be modified.

3.1 Shell Script gargle.sh

Arguments to gargle.sh are the gargle program name, the input data file to be processed, the experiment, and the VAWR name. Using these arguments, gargle.sh generates filenames and commands to process the incoming data.

Gargle.sh calls program gargle or garglenew with the filenames of the input Argos file, the VAWR table file and the output VAWR data file. Then gargle.sh sorts the new data and appends it to an archive file in the experiment subdirectory on Griffon. The archive file is then sorted by date with the UNIX sort utility, deleting duplicate entries. The sorted version of the file is placed in the processing directory for the experiment on Puli, in a file names vawrnnnn.asc.

See Appendix II for text of gargle.sh.

3.2 Program Gargle

Program gargle extracts VAWR data from a specified Argos input file based on information in a calibration file, also called a table file. The table file

contains the key to variable positions within the incoming records, allowing data to be extracted, and contains calibration values to be used in scaling the data. Program gargle writes data to a new file, and will overwrite an existing file if one is specified as the output file.

Gargle was adapted by Roger Goldsmith, of WHOI's Computer and Information Services (CIS) group. The original version, called gargoye, was written by Thomas Danforth to run under the SCO Zenix operating system on a 386 PC, and was designed to work with a commercial database. Program gargle, which runs under SunOS UNIX, uses portable ASCII data files. The specifics of program gargle are beyond the scope of this manual.

There are at present two versions of the gargle program. Programs gargle and garglenew are identical except for the handling of long wave radiation. Both versions calculate long wave from independently scaled thermopile voltage and body and dome temperatures, but garglenew uses a new algorithm. Because the new type of calibration constants were not available for the Arabian Sea VAWR, we retained the original code for the duration of that experiment. The old version will be removed after the first Arabian Sea mooring is recovered.

3.3 VAWR Table Files

Program gargle uses table files which have the same format as those used by the tape processing programs vawr.cdf and vawr.cal, but with several extensions needed to decode the Argos record. The table files control the processing of the incoming record and provide documentation of calibrations used. The use of table files provides some flexibility to the system, accommodating changes in the incoming record.

Gargle extracts the PTT numbers from the specified table file, and uses those numbers to decide which records to extract from the incoming Argos file. It also uses the position of a variable description in the table file and the length in bits specified to determine the position and length of the variable within the Argos record. The calibration values are used by gargle

to scale the raw data values, using the same algorithms as those used by the tape processing system. The minimum and maximum values for each variable specified in the table file prevent wild values from entering the data stream. This windowing can mask problems with sensors, and must be used very carefully, especially during instrument evaluation.

Comment lines in table files are denoted with a two-part forward arrow, consisting of a dash and a greater-than symbol. Variable identification lines begin with a number sign, an integer representing the variable position, a colon, and the short and long version of the name of the variable. A variable's short name is used to select the processing function to be used on the data in the field defined by the entry, and should not be modified.

See Appendix II for a sample VAWR table file.

4 Processing IMET Data

The IMET system in the GLOBEC experiment transmits hourly averages to Argos. Script `argos.sh` processes the IMET data, as it does for the VAWR data, by invoking a secondary shell script which in turn calls a C program. The shell script `imet.sh` calls program `gargle.imet`, which extracts data from the incoming file using information from a table file.

The IMET system software has the capability to handle many variables, some of which have not been implemented in the IMET hardware at this time. The program which decodes the input file produces an intermediate file, which is modified by the awk script `imet.awk` before being archived and used. In the awk script, the variable order is changed to more closely resemble the order of variables in VAWR files. The final output file has a format which is similar to the VAWR files, but has several dummy variables, which are set to 0.

The variables in the working or archive version of the IMET files are real yearday, wind east, wind north, dummy, dummy, short wave radiation,

relative humidity, barometric pressure, air temperature, sea temperature, dummy, dummy, dummy, long wave radiation, battery voltage, mooring tension, and precipitation. The units for variables which are reported by both VAWR and IMET are described above. In addition, the IMET battery voltage is recorded in amps, the mooring tension in pounds, and the precipitation sensor measures cumulative precipitation in millimeters. A sample output file is found in Appendix III.

To reprocess IMET data in case of errors, use a text editor to remove unwanted data from file `imet1.arch` in the experiment subdirectory in `/gdata/argos`. This file is appended by script `imet.sh`. After any unwanted or erroneous data has been removed, `cd` to `/gdata/argos` and type

```
imet.sh argos2.dat.nn exper instrument
```

where `nn` is the number of the `argos2.dat` file to be reprocessed, `exper` is the experiment name, and `instrument` is the instrument name, normally `imet1` or `imet2`. The experiment name must correspond to two data directories, one in `/puli/data` and one in `/gdata/argos`. The first, `/puli/data/exper`, must have a subdirectory named `argos`, and the second, `/gdata/argos/exper`, must contain a table file with the name of the instrument and the filename extension `.tbl`. Note that changes to the working data file in the experiment directory on Puli will be overwritten by the automated processing.

4.1 Shell Script `Imet.sh`

Arguments to `imet.sh` are the input filename, the experiment/directory, and the instrument name. Shell script `imet.sh` invokes program `gargle_imet` with the name of the Argos input file, the table file and the output file. The script runs the `gargle` output through an `awk` script to compute real yearday, reorder the variables and remove data with invalid dates. The `awk` script also adjusts the time of the data records to the half hour by adding

30 minutes to the reported time, and normalizes air temperatures if needed. The shell script then sorts the modified data, appends it to the archive file, sorts the archive file and copies it to the experiment's processing subdirectory in /puli/data.

See Appendix III for text of imet.sh and imet.awk.

4.2 Program Gargle_imet

Gargle_imet extracts the PTT numbers from the specified table file, and retrieves records with matching PTT numbers from the Argos file. The input records are decoded based on the length and position of each variable specified in the IMET table file. Data is converted from ASCII hexadecimal to floating point and written out in comma-separated ASCII strings. Output is to a new file, and, if an existing file is specified, it will be overwritten.

The variables output by program gargle_imet in the present implementation are: Integer day, hour, barometric pressure, air temperature, sea temperature, wind east, wind north, relative humidity, short wave radiation, long wave radiation, precipitation, battery voltage, and mooring tension. The order of these variables is modified by the shell script imet.sh, as described above.

4.3 IMET Table Files

The IMET table files are similar to the VAWR table files used by program gargle. Because IMET sensors return calibrated data in scientific units, the IMET table files do not contain calibration coefficients for most variables. They do contain information needed to decode and scale the incoming data and to control the processing itself.

At present, each Argos IMET record contains two IMET data records. To

accommodate that double record in one pass by program `gargle_imet`, the table file essentially contains two complete, identical descriptions of the IMET record. See Appendix III for a sample of an IMET table file.

5 Processing Engineering Variables

For some experiments, a separate Argos transmitter reports mooring tension from an independent tensiometer. Other variables, of interest for engineering purposes, may be included in the Argos record for these transmitters. For the Arabian Sea I experiment, variables transmitted are tension and battery voltage.

Shell script `dotens.sh` in directory `/puli/data/arab/argos` processes the data from the engineering Argos transmitter. This script is normally called with the number of the `argos.dat.n` file to be processed. If it is called with no arguments, it will process the most recent `argos.dat.n` file in directory `/gdata/argos`.

`Dotens.sh` uses the `awk` script `tens.awk` to identify tensiometer records in the incoming Argos file and to calculate year day. These fields are written to file `tens.raw`. Tension and battery voltage are ASCII hexadecimal fields, and are converted to decimal values and scaled in program `conv`. `Conv` writes the working tension file, `tens.asc`, which contains real yearday, year, month, day, hour, minute, second, tension, dummy, and battery voltage.

To reprocess tension data in case of errors, go to the processing directory for the experiment, usually on Puli. If necessary, remove any incorrect data from the database by editing file `tens.raw`, which is appended by this script, then type

```
dotens.sh nn
```

where `nn` is the number of the `argos.dat` file you wish to reprocess.

See Appendix IV for the text of `dotens.sh`, `tens.awk`, and `conv.c`.

6 Processing Position Data

Position data is processed by a separate script, and stored in a subdirectory under the usual processing directory for Argos data for each experiment. The script that processes Arabian Sea I position data, for example, is `doposit.sh`, and is found in `/puli/data/arab` in the `argos/posit` subdirectory. Position data is generated by Service Argos and incorporated into the incoming VAWR and IMET records.

Unlike meteorological data, position data seldom needs to be reprocessed, as it is not liable to contain timing errors and is not subject to calibration. However, it is often desirable to remove portions of the position record for an experiment, such as the steaming time before a mooring deployment. This allows plotting with auto-ranging axis limits, at an expanded scale, so that movement of a mooring can be monitored easily.

Argos position records contain a value indicating the quality of the calculated position, a number between one and three, with three as the highest quality. In this processing scheme, all location records are used, but the quality word is retained for future use. Including all position values, the Argos positions seem to be accurate to approximately one kilometer.

To reprocess position data, use a text editor to remove unwanted values, if necessary, from archive files in `/puli/data/exper/argos`. For GLOBEC, which generates position records for both IMET and VAWR PTTs, these files are in `/puli/data/globec/argos/posit` and are named `v1pos.arch.asc` and `ilpos.arch.asc`. For the Arabian Sea deployment, which receives only VAWR positions, the position file is `pripos.arch.asc`. After removing any incorrect data, `cd` to `/puli/data/exper/argos/posit` and reprocess by typing

```
doposit.sh nn
```

where `nn` is the number of the `argos(2).dat` file you wish to rerun. If this argument is omitted, `doposit` will process the most recent Argos file for the experiment related to the current working directory.

Position data is extracted from the Argos file by finding records in the file with a line length of 13 words and piping those records to an awk script, `posit.awk`. That script calculates real yearday, normalizes longitude to 180 degrees, and writes out PTT number, year, month, day, hour, minute, second, yearday, lat, long and a quality flag. This data is written to the temporary file `junk.dat`. The shell script then checks this file for the desired PTT numbers, and if any exist, appends the position record, stripped of the PTT number, to the appropriate archive file. This file is then sorted and the output written over the working version of the position file. For the Arabian Sea experiment, that file is `/puli/data/arab/argos/posit/arab1.pos`.

See Appendix V for the text of `doposit.sh` and `posit.awk`.

7 Data Transmission Scripts

To automatically distribute data to hosts with anonymous ftp accounts, `ftp` is run from the shell script `ftp.sh`, invoked by `argos.sh`. The script uses the `-n` and `-i` flags, which allow non-interactive use of `ftp`, redirecting input commands from the text of the script itself. For sites receiving data via `ftp`, we transmit the entire working version of the data every day, overwriting the data previously sent.

For hosts without anonymous ftp sites, we use the UNIX mail utility to distribute the data. When using mail, we send only updates to the data. Since we want to be sure to send a full day's worth of data, we use the UNIX utility `tail` to extract the last 100 records from the working version of the data files. In the current implementation, we extract variables of interest for our mail recipients, using an awk script, `x.awk`. We prepend a header record identifying the data as ours, and a record containing the variable names, before invoking mail.

See Appendix VI for the text of the scripts used to distribute Argos data. Note that the hosts names and IP addresses have been changed in the scripts reproduced there, for security purposes. These scripts can be run manually to retransmit data if necessary.

8 Plotting Scripts

Plots of all incoming data are generated and printed automatically on weekday mornings. The plotting scripts, which can be different for each experiment, are found with the processed data in the experiment subdirectories, currently on the workstation Puli. The program Plot Plus, written by Donald Denbo of NOAA's Pacific Marine Environmental Laboratory, is used to create multi-panel plots of instrument data. Maps of mooring locations are created using Matlab, a commercial numerical software package.

Plots of Argos data are used to monitor both meteorology and instrumentation, so we display the variables of meteorological interest on a separate plot from those of engineering interest. The scripts that create these plots are described here, see Appendix VII for examples.

8.1 Plot Plus Time Series Plots

8.1.1 Scientific Variables Plot

The command file `argoss.ppc` is used with program `pplus` to plot VAWR Argos meteorological data. The arguments are start day, end day, and input filename. The automated processing system invokes this script with a 3-day time span ending on the current day provided by the UNIX date utility.

See Appendix VII.2 for the text of the script `argoss.ppc` and a sample output plot.

8.1.2 Engineering Variables Plot

The `pplus` command file `argose.ppc` plots the variables that are of interest primarily for engineering purposes. Some of these variables are reported by the VAWR, some by the IMET or the tension recorder, depending on the Argos configuration for each experiment. The arguments are identical to the arguments for `argoss.ppc`, above. See Appendix VII.3 for the text of `argose.ppc` and a sample output plot.

8.2 Matlab Position Plot

Matlab script `posit1.m` is used to plot Argos positions. Because it is essential to see the most recent position value, we allow the plot to self-scale. This assures that any change in position will be very visible on the final plot, not cropped because it is out-of-bounds.

For some experiments, a watch circle is overplotted on the positions. This indicates the calculated limits of the mooring line, and is based on the depth of the mooring. Care must be used when plotting watch circles, however, since the accuracy of the Argos position information is only about one kilometer. For deep-water moorings, like the Arabian Sea, this is sufficient for the large watch circle of over 3 km. For a shallow mooring like GLOBEC, with its watch circle of about 40 meters, the Argos error exceeds the expected watch circle, so the watch circle is not plotted.

See Appendix VII.4 for the text of the Matlab position script, and sample output plots.

fi

```

Appendix I.2. Shell Script Findlast.sh

This script works with groups of files with three-part names, where the parts of the names are separated by periods, and the third part of the name is a version number. It will find the file with name matching the two parts specified in argument 1 with the highest version number on disk. Findlast is called by argos.sh and dposit.sh, but it can also be invoked from the keyboard to determine the number of the most recent argos.dat or argos2.dat file. It returns only the number of the file, not the complete filename.

```
#!/bin/sh
# find the files in the argument and return the number of highest
# version number.
# based on filenames file.ext.1 file.ext.2 .... file.ext.n
#
# modified 950124 to handle deleted data files by using the version
# number instead of relying on creation date of file
#
if [ $# -eq 0 ]
then
    echo -1
    exit
fi
ls $1* |awk 'BEGIN {FS="."}{print $3}' |sort +0 -n |tail -1
```

Appendix II. VAWR Processing

Appendix II.1. Shell Script gargle.sh

```
#!/bin/sh
# gargle.sh: run one of the gargle programs and process the output
# usage:          gargle.sh program argosfilename experiment vawrname
# example:       gargle.sh garglenew argos2.dat.1 globec vawr0707
# 941208 n. galbraith
# arguments:
# $1 program to run   garglenew           must be in /gdata/argos/src
# $2 inputfile       argos2.dat.1         must be in /gdata/argos
# $3 experiment      globec              subdirectory/eperiment
# $4 vawrnam        vawr0707            table file in subdir named in $3
cd /gdata/argos # go to incoming data spot
src/$1 $2 $3/$4.tbl $3/$4.raw # run garglenew or gargle
sort +0 -1 -u -n $3/$4.raw > $3/$4.asc # remove incoming dupes
cat $3/$4.asc >> $3/$4.arch # archive, remove duplicates and
# send to processing dir
sort +0 -1 -u -n $3/$4.arch > /puli/data/$3/argos/$4.asc
```

Appendix II.2. Gargle output

This is a sample output file containing VAWR data as written by program gargle. The variables are:
